Introduction to Near-Term Quantum Computing
情報科学科特別講義Ⅱ/量子計算論入門
2024年度の計画

Path to the Utility era in Quantum Computing

The goal of this course is to learn how to implement utility-scale applications on a quantum computer. To achieve the goal, the course covers from the basics of quantum information to recent advances of quantum algorithms for noisy quantum devices as well as circuit optimization and error mitigation techniques. The course also introduces how to implement quantum algorithms using open-source framework of quantum computing and real quantum device with more than 127 qubits. The course is intended to help students understand the potential and limitations of currently available quantum devices.

Schedule: Every Friday from 16:50 to 18:20 (except May 15 (Wed), May 30(Thu))

Notes: All lectures will be held in person. Recording also will be available for reviewing.

Course Schedule 2024

Date	Lecture Title	Lecturer	Date	Lecture Title	Lecturer
4/5	Invitation to the Utility era	Tamiya Onodera	6/7	Classical simulation (Clifford circuit, tensor network)	Yoshiaki Kawase
4/19	Quantum Gates, Circuits, and Measurements	Kifumi Numata	6/14	Quantum Hardware	Masao Tokunari
4/26	LOCC (Quantum teleportation/superdense coding/Remote CNOT)	Kifumi Numata/ Atsushi Matsuo	6/21	Quantum circuit optimization (transpilation)	Toshinari Itoko
5/10	Quantum Algorithms: Grover's algorithm	Atsushi Matsuo	6/28	Quantum noise and quantum error mitigation	Toshinari Itoko
5/15 (Wed)	Quantum Algorithms: Phase estimation	Kento Ueda	7/5	Quantum Utility I (127Qubit GHZ)	Kifumi Numata
5/24	Quantum Algorithms: Variational Quantum Algorithms (VQA)	Takashi Imamichi	7/12	Quantum Utility II (Utility paper implementation)	Tamiya Onodera
5/30 (Thu)	Quantum simulation (Ising model, Heisenberg, XY model), Time evolution (Suzuki Trotter, QDrift)	Yukio Kawashima	7/19	Quantum Utility III (Krylov subspace expansion)	Yukio Kawashima

The topics of today's class

Studying three types of classical simulation:

- (State Vector)
- Tensor Network
Matrix Product State
- Stabilizer
Clifford Circuit, a circuit consisting of H, S and CNOT gates

State vector simulation

An n -qubit quantum state is represented by

$$|\psi\rangle = \sum_{\sigma_1, \dots, \sigma_n} c_{\sigma_1 \dots \sigma_n} |\sigma_1 \dots \sigma_n\rangle,$$

where c_i is a complex number and $\sum_{i=0}^{2^n-1} |c_i|^2 = 1$ is satisfied.

Since the length of state vector is 2^n ,
the time and space complexity increase exponentially with the number of qubits.

Applying a single qubit gate (state vector simulation)

A single qubit gate can be written by

$$\begin{aligned} \mathbf{U}_t &= \begin{pmatrix} u_{00} & u_{01} \\ u_{10} & u_{11} \end{pmatrix} \\ &= u_{00}|0\rangle\langle 0| + u_{10}|1\rangle\langle 0| + u_{01}|0\rangle\langle 1| + u_{11}|1\rangle\langle 1|, \end{aligned}$$

where $\mathbf{U}_t \mathbf{U}_t^\dagger = \mathbf{U}_t^\dagger \mathbf{U}_t = I$ is satisfied.

Here, we apply a single qubit gate $I \otimes \cdots \otimes I \otimes \mathbf{U}_t \otimes I \otimes \cdots \otimes I$ to a quantum state:

$$\begin{aligned} I \otimes \cdots \otimes I \otimes \mathbf{U}_t \otimes I \otimes \cdots \otimes I |\psi\rangle &= \sum_{\sigma_1, \dots, \sigma_t, \dots, \sigma_n} (I \otimes \cdots \otimes I \otimes \mathbf{U}_t \otimes I \otimes \cdots \otimes I) c_{\sigma_1 \dots \sigma_t \dots \sigma_n} |\sigma_1 \cdots \sigma_t \cdots \sigma_n\rangle \\ &= \sum_{\sigma_1, \dots, \sigma_{t-1}, \sigma_{t+1}, \dots, \sigma_n} \left(\sum_{\sigma_t=0}^1 \mathbf{U}_t c_{\sigma_1 \dots \sigma_t \dots \sigma_n} |\sigma_t\rangle \right) |\sigma_1 \cdots \sigma_{t-1} \sigma_{t+1} \cdots \sigma_n\rangle \\ &= \sum_{\sigma_1, \dots, \sigma_t, \dots, \sigma_n} (u_{0\sigma_t} + u_{1\sigma_t}) c_{\sigma_1 \dots \sigma_t \dots \sigma_n} |\sigma_1 \cdots \sigma_t \cdots \sigma_n\rangle \end{aligned}$$

We need $O(2^n)$ to update all the elements of the state vector.

Applying CNOT gate (using a state vector)

CNOT gate can be written by

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix} = |0\rangle\langle 0| \otimes I + |1\rangle\langle 1| \otimes X.$$

swap  $\begin{pmatrix} c_{00} \\ c_{01} \\ c_{10} \\ c_{11} \end{pmatrix}$

If we apply a CNOT gate to a n -qubit quantum state $|\psi\rangle$ with c th control qubit and t th target qubit, the quantum state becomes

$$\begin{aligned} & (I_1 \otimes \cdots \otimes I_{c-1} \otimes |0\rangle\langle 0| \otimes I_{c+1} \otimes \cdots \otimes I_{t-1} \otimes I_t \otimes I_{t+1} \otimes \cdots \otimes I_n \\ & + I_1 \otimes \cdots \otimes I_{c-1} \otimes |1\rangle\langle 1| \otimes I_{c+1} \otimes \cdots \otimes I_{t-1} \otimes X_t \otimes I_{t+1} \otimes \cdots \otimes I_n) |\psi\rangle \\ & = \sum_{\sigma_1, \dots, \sigma_c, \dots, \sigma_t, \dots, \sigma_n} c_{\sigma_1 \dots \sigma_c \dots (\sigma_c \oplus \sigma_t) \dots \sigma_n} |\sigma_1 \dots \sigma_c \dots \sigma_t \dots \sigma_n\rangle. \end{aligned}$$

t th

So, we need $O(2^n)$ to update all the elements of the quantum state.

The calculation of inner-products (using state vector)

Inner product between two quantum states is calculated by

$$\begin{aligned}\langle \psi' | \psi \rangle &= \sum_{\substack{\sigma_1, \dots, \sigma_n \\ \sigma'_1 \dots \sigma'_n}} \langle \sigma'_1 \dots \sigma'_n | c'^*_{\sigma'_1 \dots \sigma'_n} c_{\sigma_1 \dots \sigma_n} | \sigma_1 \dots \sigma_n \rangle \\ &= \sum_{\substack{\sigma_1, \dots, \sigma_n \\ \sigma'_1 \dots \sigma'_n}} c'^*_{\sigma'_1 \dots \sigma'_n} c_{\sigma_1 \dots \sigma_n} \delta_{\sigma_1, \sigma'_1} \dots \delta_{\sigma_n, \sigma'_n} \\ &= \sum_{\sigma_1, \dots, \sigma_n} c'^*_{\sigma_1 \dots \sigma_n} c_{\sigma_1 \dots \sigma_n}\end{aligned}$$

We need $O(2^n)$.

Disadvantage of state vector simulation

Disadvantage of state vector simulation:

The length of state vector $O(2^n)$

Updating the state vector applied by a single qubit gate $O(2^n)$

We will present a classical simulation method using Matrix Product States to perform more efficient classical simulation.

Tensor

- Scalar: s
(rank-0 tensor)
- Vector: $\mathbf{V} = (V_1, V_2, \dots, V_n)$
(rank-1 tensor)
- Matrix:
(rank-2 tensor)

$$\mathbf{M} = \begin{pmatrix} M_{11} & \dots & M_{1n} \\ \vdots & \ddots & \vdots \\ M_{n1} & \dots & M_{nn} \end{pmatrix}$$

- Rank-3 tensor: \mathbf{T}_{ijk} or \mathbf{T}_{ij}^k

In this lecture, we regard these tensors representing the same tensor.

Tensor Contraction

Inner product:

$$\mathbf{U} \cdot \mathbf{V} = \sum_i U_i V_i$$

Matrix Vector Product:

$$V_i = \sum_j M_{ij} U_j$$

Trace:

$$\text{Tr } \mathbf{M} = \sum_i M_{ii}$$

$$\mathbf{U} = (U_1, \dots, U_n), \mathbf{V} = (V_1, \dots, V_n), \mathbf{M} = \begin{pmatrix} M_{11} & \dots & M_{1n} \\ \vdots & \ddots & \vdots \\ M_{n1} & \dots & M_{nn} \end{pmatrix}$$

Tensor Contraction

$$\sum_j T_{ijk} V_{jl}$$

$$\sum_j T_{ijk} \delta_{jl} = T_{ilk}$$

||

Identity matrix

$$\begin{array}{c} j \\ | \\ l \end{array} = \delta_{jl}$$

Tensor Decomposition Using Singular Value Decomposition

$$A_{ij} = \sum_{k=1}^s \sum_{l=1}^s U_{ik} (D_k \delta_{kl}) V_{jl}^{\dagger} = \sum_{k=1}^s U_{ik} D_k V_{jk}^{\dagger}$$

Matrix Product State (MPS)

$$|\psi\rangle = \sum_{\substack{\sigma_1 \sigma_2 \sigma_3, \\ b_1 b_2}} A_{b_1}^{\sigma_1} B_{b_1 b_2}^{\sigma_2} C_{b_2}^{\sigma_3} |\sigma_1 \sigma_2 \sigma_3\rangle$$

This is useful for representing one-dimensional quantum systems.

Example of Matrix Product State

Representing 3 qubit GHZ state using Matrix Product State:

$$\begin{aligned} |\psi\rangle &= \frac{1}{\sqrt{2}} (|000\rangle + |111\rangle) \\ &= \frac{1}{\sqrt{2}} (1 \ 0) \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} |000\rangle + \frac{1}{\sqrt{2}} (1 \ 0) \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} |001\rangle + \frac{1}{\sqrt{2}} (1 \ 0) \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} |010\rangle \\ &\quad + \frac{1}{\sqrt{2}} (1 \ 0) \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} |011\rangle + \frac{1}{\sqrt{2}} (0 \ 1) \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} |100\rangle + \frac{1}{\sqrt{2}} (0 \ 1) \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} |101\rangle \\ &\quad + \frac{1}{\sqrt{2}} (0 \ 1) \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} |110\rangle + \frac{1}{\sqrt{2}} (0 \ 1) \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix} |111\rangle \end{aligned}$$

$$|\psi\rangle = \sum_{\sigma_1, \sigma_2, \sigma_3, b_1, b_2} A_{b_1}^{\sigma_1} B_{b_1, b_2}^{\sigma_2} C_{b_2}^{\sigma_3} |\sigma_1 \sigma_2 \sigma_3\rangle,$$

where $\sigma_1 \in \{0,1\}, \sigma_2 \in \{0,1\}, \sigma_3 \in \{0,1\}$,

$$A_{b_1}^0 = (1 \ 0), A_{b_1}^1 = (0 \ 1), B_{b_1, b_2}^0 = \begin{pmatrix} 1/\sqrt{2} & 0 \\ 0 & 0 \end{pmatrix}, B_{b_1, b_2}^1 = \begin{pmatrix} 0 & 0 \\ 0 & 1/\sqrt{2} \end{pmatrix}, C_{b_2}^0 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, C_{b_2}^1 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

Matrix Product Operator

Matrix Product Operator is written by

$$\hat{O} = \sum_{\substack{\sigma_1, \sigma_2, \sigma_3, \sigma_4 \\ \sigma'_1, \sigma'_2, \sigma'_3, \sigma'_4 \\ w_1, w_2, w_3}} A_{w_1}^{\sigma_1, \sigma'_1} B_{w_1, w_2}^{\sigma_2, \sigma'_2} C_{w_2, w_3}^{\sigma_3, \sigma'_3} D_{w_3}^{\sigma_4, \sigma'_4} .$$

Matrix Product Operator is used for applying quantum gates and evaluating expectation values.

Applying a single qubit gate (using MPS)

A single qubit gate can be represented by

$$U^{\sigma_t, \sigma'_t} = u_{00}|0\rangle\langle 0| + u_{10}|1\rangle\langle 0| + u_{01}|0\rangle\langle 1| + u_{11}|1\rangle\langle 1| = \sum_{\sigma'_t=0}^1 \sum_{\sigma_t=0}^1 u_{\sigma'_t \sigma_t} |\sigma'_t\rangle\langle \sigma_t|.$$

A quantum state applied by a single qubit gate $I \otimes \cdots \otimes I \otimes U_t \otimes I \otimes \cdots \otimes I$ is described by

$$(I \otimes \cdots \otimes I \otimes U_t \otimes I \otimes \cdots \otimes I) |\psi\rangle$$

$$= \sum_{\sigma_1, \dots, \sigma_n, \sigma'_1, \dots, \sigma'_n, b_1, \dots, b_{n-1}} \left(I^{\sigma_1 \sigma'_1} \dots I^{\sigma_{t-1} \sigma'_{t-1}} U^{\sigma_t \sigma'_t} I^{\sigma_{t+1} \sigma'_{t+1}} \dots I^{\sigma_n \sigma'_n} \right) T^{(1)}_{b_1}^{\sigma_1} T^{(2)}_{b_1, b_2}^{\sigma_2} \dots T^{(n-1)}_{b_{n-2}, b_{n-1}}^{\sigma_{n-1}} T^{(n)}_{b_{n-1}}^{\sigma_n} |\sigma_1 \cdots \sigma_n\rangle,$$

Applying a single qubit gate (using MPS)

$$\begin{aligned}
 & (I \otimes \cdots \otimes I \otimes U_t \otimes I \otimes \cdots \otimes I) |\psi\rangle \\
 &= \sum_{\substack{\sigma_1, \dots, \sigma_n, b_1, \dots, b_{n-1} \\ \sigma'_1, \dots, \sigma'_n}} \left(I^{\sigma_1 \sigma'_1} \cdots I^{\sigma_{t-1} \sigma'_{t-1}} U^{\sigma_t \sigma'_t} I^{\sigma_{t+1} \sigma'_{t+1}} \cdots I^{\sigma_n \sigma'_n} \right) T^{(1)}_{b_1}^{\sigma_1} T^{(2)}_{b_1, b_2}^{\sigma_2} \cdots T^{(n-1)}_{b_{n-2}, b_{n-1}}^{\sigma_{n-1}} T^{(n)}_{b_{n-1}}^{\sigma_n} |\sigma_1 \cdots \sigma_n\rangle, \\
 &= \sum_{\substack{\sigma'_1, \dots, \sigma'_n \\ b_1, \dots, b_{n-1}}} T^{(1)}_{b_1}^{\sigma'_1} \cdots T^{(t-1)}_{b_{t-2}, b_{t-1}}^{\sigma'_{t-1}} \underbrace{\left(\sum_{\sigma_t=0}^1 U^{\sigma_t, \sigma'_t} T^{(t)}_{b_{t-1}, b_t}^{\sigma_t} |\sigma_t\rangle \right)}_{\text{We only need to update these terms.}} T^{(t+1)}_{b_t, b_{t+1}}^{\sigma'_{t+1}} \cdots T^{(n)}_{b_{n-1}}^{\sigma'_n} |\sigma'_1 \cdots \sigma'_{t-1} \sigma'_{t+1} \cdots \sigma'_n\rangle
 \end{aligned}$$

We only need to update these terms.

d : the dimension of σ_i
 m : the dimension of b_i

The computational complexity is $O(d^2 m^2) \ll O(2^n)$.

State vector simulation ($d=2$)

Applying CNOT gate (using MPS)

A CNOT gate is also represented by

$$A^{\sigma_c, \sigma_t, \sigma'_c, \sigma'_t} := \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}$$

$(\sigma_c, \sigma_t) = (0,0), (0,1), (1,0), (1,1)$

(σ'_c, σ'_t)

← $(0,0)$

← $(0,1)$

← $(1,0)$

← $(1,1)$

Applying a CNOT gate (using MPS)

A quantum state applied by CNOT gate with c th control qubit and t th target qubit is updated by

$$(I_1 \otimes \cdots \otimes I_{c-1} \otimes |0\rangle\langle 0| \otimes I_{c+1} \otimes \cdots \otimes I_{t-1} \otimes I_t \otimes I_{t+1} \otimes \cdots \otimes I_n \\ + I_1 \otimes \cdots \otimes I_{c-1} \otimes |1\rangle\langle 1| \otimes I_{c+1} \otimes \cdots \otimes I_{t-1} \otimes X_t \otimes I_{t+1} \otimes \cdots \otimes I_n) |\psi\rangle$$

$$= \sum_{\substack{\sigma'_1, \dots, \sigma'_n \\ b_1, \dots, b_{n-1}}} \left(\sum_{\sigma_c, \sigma_t} A^{\sigma_c, \sigma_t, \sigma'_c, \sigma'_t} T^{(c)}_{b_{c-1}, b_c}{}^{\sigma_c} T^{(t)}_{b_{t-1}, b_t}{}^{\sigma_t} |\sigma_c \sigma_t\rangle \right) \\ T^{(1)}_{b_1}{}^{\sigma'_1} T^{(2)}_{b_1, b_2}{}^{\sigma'_2} \cdots T^{(c-1)}_{b_{c-2}, b_{c-1}}{}^{\sigma'_{c-1}} T^{(c+1)}_{b_c, b_{c+1}}{}^{\sigma'_{c+1}} \cdots T^{(t-1)}_{b_{t-2}, b_{t-1}}{}^{\sigma'_{t-1}} T^{(t+1)}_{b_t, b_{t+1}}{}^{\sigma'_{t+1}} \cdots T^{(n-1)}_{b_{n-2}, b_{n-1}}{}^{\sigma'_{n-1}} T^{(n)}_{b_{n-1}}{}^{\sigma'_n} |\sigma'_1 \cdots \sigma'_{c-1} \sigma'_{c+1} \cdots \sigma'_{t-1} \sigma'_{t+1} \cdots \sigma'_n\rangle$$

We only need to update these terms.

The computational complexity is $O(d^4 m^4) \ll O(2^n)$.

 State vector simulation (d=2)

Decomposition

A quantum state is represented by the following formula:

$$|\psi\rangle = \sum_{\sigma_1, \dots, \sigma_n} c_{\sigma_1, \dots, \sigma_n} |\sigma_1\rangle \cdots |\sigma_n\rangle.$$

We would like to turn it into MPS form.

First, we use singular value decomposition(SVD) to decompose the system of first qubit and the other part.

To this end, we make a matrix consisting of the coefficients $c_{\sigma_1, \dots, \sigma_n}$, and apply SVD to this matrix:

$$\begin{aligned} & \begin{pmatrix} c_{0,0,\dots,0} & \cdots & c_{0,d-1,\dots,d-1} \\ \vdots & \ddots & \vdots \\ c_{d-1,0,\dots,0} & \cdots & c_{d-1,d-1,\dots,d-1} \end{pmatrix} = UDV^\dagger \\ & = \begin{pmatrix} u_{0,0} & \cdots & u_{0,r-1} \\ \vdots & \ddots & \vdots \\ u_{d-1,0} & \cdots & u_{d-1,r-1} \end{pmatrix} \begin{pmatrix} \lambda_0 & & \\ & \ddots & \\ & & \lambda_{r-1} \end{pmatrix} \begin{pmatrix} v_{0,0,\dots,0} & \cdots & v_{0,d-1,\dots,d-1} \\ \vdots & \ddots & \vdots \\ v_{r-1,0,\dots,0} & \cdots & v_{r-1,d-1,\dots,d-1} \end{pmatrix} \\ & c_{\sigma_1, \dots, \sigma_n} = \sum_{k=0}^{r-1} u_{\sigma_1, k} \lambda_k v_{k, \sigma_2, \dots, \sigma_n}, \forall \sigma_2, \dots, \sigma_n \in \{0, \dots, d-1\}, \end{aligned}$$

where r is the rank of diagonal matrix D .

Decomposition

$$c_{\sigma_1, \dots, \sigma_n} = \sum_{k=0}^{r-1} u_{\sigma_1, k} \lambda_k v_{k, \sigma_2, \dots, \sigma_n}, \forall \sigma_2, \dots, \sigma_n \in \{0, \dots, d-1\},$$

We assign this expression to the initial formula:

$$|\psi\rangle = \sum_{k=0}^{r-1} \sum_{\sigma_1=0}^{d-1} u_{\sigma_1, k} \lambda_k |\sigma_1\rangle \sum_{\sigma_2, \dots, \sigma_n} v_{k, \sigma_2, \dots, \sigma_n} |\sigma_2\rangle \cdots |\sigma_n\rangle.$$

We repeatedly apply SVD to $v_{k, \sigma_2, \dots, \sigma_n}$, we obtain

$$|\psi\rangle = \sum_{\substack{\sigma_1, \dots, \sigma_n \\ k_1, \dots, k_{n-1}}} u_{\sigma_1, k_1}^{(1)} \lambda_{k_1}^{(1)} u_{k_1, \sigma_2, k_2}^{(2)} \lambda_{k_2}^{(2)} \cdots \lambda_{k_{n-1}}^{(n-1)} u_{\sigma_n, k_{n-1}}^{(n)} |\sigma_1\rangle |\sigma_2\rangle \cdots |\sigma_n\rangle.$$

We can rewrite a quantum state into MPS form using SVD.

Inner Product between two MPSs

$$\begin{aligned}
 \langle \psi' | \psi \rangle &= \left(\sum_{\substack{\sigma'_1 \dots \sigma'_n \\ b'_1 \dots b'_{n-1}}} \langle \sigma'_1 \dots \sigma'_n | T'^{(n)}_{b'_{n-1}}{}^{\sigma'_n \dagger} T'^{(n-1)}_{b'_{n-1} b'_{n-2}}{}^{\sigma'_{n-1} \dagger} \dots T'^{(2)}_{b'_2 b'_1}{}^{\sigma'_2 \dagger} T'^{(1)}_{b'_1}{}^{\sigma'_1 \dagger} \right) \\
 &\quad \left(\sum_{\substack{\sigma_1 \dots \sigma_n \\ b_1 \dots b_{n-1}}} T^{(1)}_{b_1}{}^{\sigma_1} T^{(2)}_{b_1 b_2}{}^{\sigma_2} \dots T^{(n-1)}_{b_{n-2} b_{n-1}}{}^{\sigma_{n-1}} T^{(n)}_{b_{n-1}}{}^{\sigma_n} | \sigma_1 \dots \sigma_n \rangle \right) \\
 &= \sum_{\substack{\sigma'_1 \dots \sigma'_n \\ b'_1 \dots b'_{n-1}}} \sum_{\substack{\sigma_1 \dots \sigma_n \\ b_1 \dots b_{n-1}}} T'^{(n)}_{b'_{n-1}}{}^{\sigma'_n \dagger} T'^{(n-1)}_{b'_{n-1} b'_{n-2}}{}^{\sigma'_{n-1} \dagger} \dots T'^{(2)}_{b'_2 b'_1}{}^{\sigma'_2 \dagger} T'^{(1)}_{b'_1}{}^{\sigma'_1 \dagger} T^{(1)}_{b_1}{}^{\sigma_1} T^{(2)}_{b_1 b_2}{}^{\sigma_2} \dots T^{(n-1)}_{b_{n-2} b_{n-1}}{}^{\sigma_{n-1}} T^{(n)}_{b_{n-1}}{}^{\sigma_n} \delta_{\sigma'_1 \sigma_1} \dots \delta_{\sigma'_n \sigma_n} \\
 &= \sum_{\substack{b'_1 \dots b'_{n-1}}} \sum_{\substack{\sigma_1 \dots \sigma_n \\ b_1 \dots b_{n-1}}} T'^{(n)}_{b'_{n-1}}{}^{\sigma'_n \dagger} T'^{(n-1)}_{b'_{n-1} b'_{n-2}}{}^{\sigma'_{n-1} \dagger} \dots T'^{(2)}_{b'_2 b'_1}{}^{\sigma'_2 \dagger} T'^{(1)}_{b'_1}{}^{\sigma'_1 \dagger} T^{(1)}_{b_1}{}^{\sigma_1} T^{(2)}_{b_1 b_2}{}^{\sigma_2} \dots T^{(n-1)}_{b_{n-2} b_{n-1}}{}^{\sigma_{n-1}} T^{(n)}_{b_{n-1}}{}^{\sigma_n}
 \end{aligned}$$

We will perform the remaining calculations by using diagrams.

An example of calculating Inner Product using MPS

$$\sum_{\sigma_3,b_2,b'_2} C'_{b'_2}{}^{\sigma_3\dagger} B''_{b_2b'_2} C_{b_2}^{\sigma_3}$$

$$\sum_{b_2=1}^m T''_{b_{n-1},b'_{n-1}}{}^{(n-1)} T^{(n)}_{b_{n-1}}{}^{\sigma_n} =: T'''_{b'_{n-1}}{}^{(n-1)}{}^{\sigma_n}$$

cost: dm^2

$$\sum_{\sigma_3=1}^d \sum_{b'_2=1}^m T'_{b'_2}{}^{\sigma_3\dagger} T'''_{b'_{n-1}}{}^{(n-1)}{}^{\sigma_n}$$

cost: dm

An example of calculating Inner Product using MPS

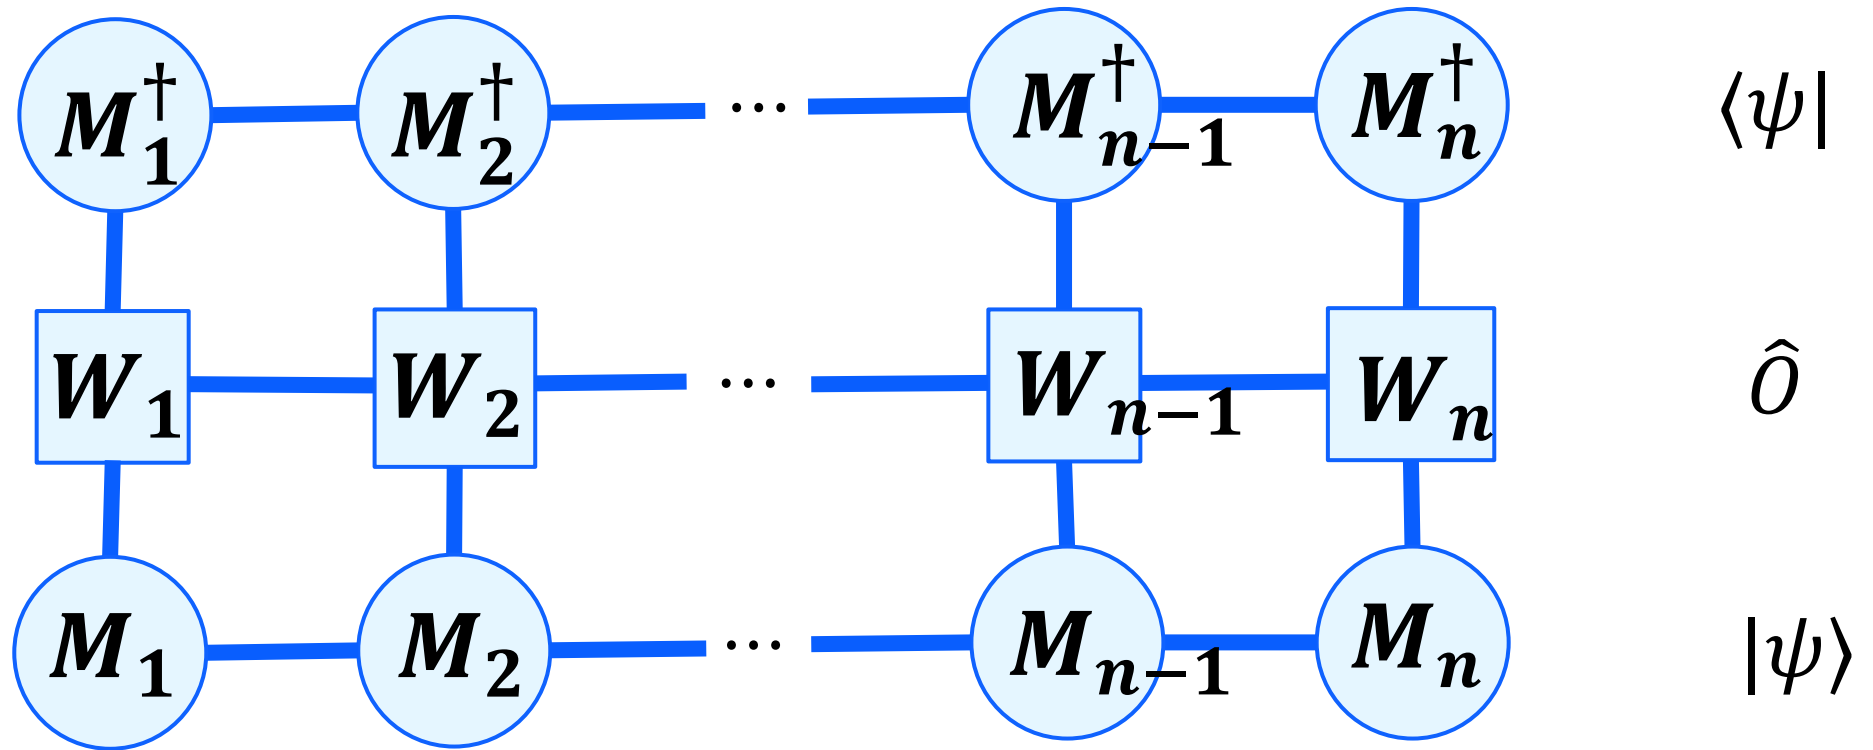

The total cost:

$$O(ndm^3) \ll O(2^n)$$

where n is the number of qubits

MPS allows us to calculate inner products more efficiently than state vector simulation.

The expectation values of MPS

We can calculate expectation values similar to calculating inner-products.
Computational complexity is

$$O(n(m^3kd + m^2k^2d^2)) \ll O(2^n).$$

MPS also efficiently calculate expectation values.

k is a typical dimension of
Matrix Product Operator

Clifford Circuit

Pauli Operator and Pauli Group

– Pauli Operator

$$\mathbf{I} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \quad \mathbf{X} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \mathbf{Y} = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \quad \mathbf{Z} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

Pauli group is defined by

$$\mathcal{P}_n = \{c \mathbf{P}_1 \otimes \cdots \otimes \mathbf{P}_j \otimes \cdots \otimes \mathbf{P}_n \mid c = \pm 1, \pm i ; \mathbf{P}_j = \mathbf{I}, \mathbf{X}, \mathbf{Y}, \mathbf{Z}\}.$$

Examples:

$$i\mathbf{Y} \otimes \mathbf{X} \in \mathcal{P}_2, -\mathbf{X} \otimes \mathbf{Y} \otimes \mathbf{Z} \in \mathcal{P}_3$$

Clifford Gates and Clifford Group

Clifford Gates

$$\mathbf{H} = \begin{pmatrix} 1/\sqrt{2} & 1/\sqrt{2} \\ 1/\sqrt{2} & -1/\sqrt{2} \end{pmatrix} \quad \mathbf{S} = \begin{pmatrix} 1 & 0 \\ 0 & i \end{pmatrix} \quad \mathbf{CX} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}$$

Clifford gates are elements of the following Clifford group \mathcal{C}_n

$$\mathcal{C}_n = \{V \in U_n | VQ_nV^\dagger = Q'_n, \forall Q_n \in \mathcal{P}_n, Q'_n \in \mathcal{P}_n\}$$

for n -qubit Unitary U_n , the elements of Pauli group Q'_n

Clifford gates map the elements of Pauli group to itself. For example,

$$\begin{aligned} \mathbf{H}\mathbf{X}\mathbf{H} &= \mathbf{Z}, \mathbf{S}\mathbf{Y}\mathbf{S}^\dagger = -\mathbf{X}, \mathbf{S}\mathbf{Z}\mathbf{S}^\dagger = \mathbf{Z}, \\ (\mathbf{CX})(\mathbf{I} \otimes \mathbf{Z})(\mathbf{CX}) &= \mathbf{Z} \otimes \mathbf{Z}. \end{aligned}$$

Stabilizer state

A stabilizer state is used to efficiently simulate the Clifford circuit.

A stabilizer state is a quantum state with +1 eigen value for a Pauli term.

$$X|+\rangle = |+\rangle = \frac{|0\rangle + |1\rangle}{\sqrt{2}}, Y|i\rangle = |i\rangle = \frac{|0\rangle + i|1\rangle}{\sqrt{2}}, Z|0\rangle = |0\rangle$$

Pauli X , Y , and Z stabilize $|+\rangle$, $|i\rangle$, and $|0\rangle$, respectively.

A stabilizer state can be uniquely determined by n stabilizer operators.

	$+XX$	$-XX$
$+ZZ$	$\frac{ 00\rangle + 11\rangle}{\sqrt{2}}$	$\frac{ 00\rangle - 11\rangle}{\sqrt{2}}$
$-ZZ$	$\frac{ 01\rangle + 10\rangle}{\sqrt{2}}$	$\frac{ 01\rangle - 10\rangle}{\sqrt{2}}$

Binary representation of Pauli terms

We introduce a binary representation of Pauli terms to efficiently simulate Clifford circuit.

We transform $\mathbf{P}_1 \otimes \cdots \otimes \mathbf{P}_i \otimes \cdots \otimes \mathbf{P}_n$ into $x_1 \cdots x_i \cdots x_n z_1 \cdots z_i \cdots z_n$, where $\mathbf{P}_i \in \{\mathbf{I}, \mathbf{X}, \mathbf{Y}, \mathbf{Z}\}$, $x_i \in \{0,1\}$, $z_i \in \{0,1\}$ for $i = 1, \dots, n$.

$$\begin{aligned} \mathbf{P}_i = \mathbf{I} &\Rightarrow x_i = 0, z_i = 0 \\ \mathbf{P}_i = \mathbf{X} &\Rightarrow x_i = 1, z_i = 0 \\ \mathbf{P}_i = \mathbf{Y} &\Rightarrow x_i = 1, z_i = 1 \\ \mathbf{P}_i = \mathbf{Z} &\Rightarrow x_i = 0, z_i = 1 \end{aligned}$$

For example,

	$x_1 x_2 x_3 x_4$	$z_1 z_2 z_3 z_4$
$X_1 Y_2 Z_3 I_4$	1100	0110

For simplicity, we ignore the phase.

Applying Clifford gates using binary representation

Applying H gate on t -th qubit

$x_{11}x_{12} \cdots x_{1t} \cdots x_{1n}$	$z_{11}z_{12} \cdots z_{1t} \cdots z_{1n}$
\vdots	\vdots
$x_{i1}x_{i2} \cdots x_{it} \cdots x_{in}$	$z_{i1}z_{i2} \cdots z_{it} \cdots z_{in}$
\vdots	\vdots
$x_{n1}x_{n2} \cdots x_{nt} \cdots x_{nn}$	$z_{n1}z_{n2} \cdots z_{nt} \cdots z_{nn}$

swap

$$x_{it}^{new} = z_{it}, z_{it}^{new} = x_{it}, \text{ for } i = 1, \dots, n$$

Applying S gate on t -th qubit

$x_{11}x_{12} \cdots x_{1t} \cdots x_{1n}$	$z_{11}z_{12} \cdots z_{1t} \cdots z_{1n}$
\vdots	\vdots
$x_{i1}x_{i2} \cdots x_{it} \cdots x_{in}$	$z_{i1}z_{i2} \cdots z_{it} \cdots z_{in}$
\vdots	\vdots
$x_{n1}x_{n2} \cdots x_{nt} \cdots x_{nn}$	$z_{n1}z_{n2} \cdots z_{nt} \cdots z_{nn}$

Apply exclusive-OR

$$z_{it}^{new} = z_{it} \oplus x_{it}, \text{ for } i = 1, \dots, n$$

We can apply H or S gate by updating the binary table in $O(n)$.

Example of applying H or S gate

$|00\rangle$ is stabilized by $+IZ$ and $+ZI$.

Here, we act H gate on 1st qubit.

X_1I_2 and I_1Z_2 stabilize $|0\rangle \otimes \frac{|0\rangle+|1\rangle}{\sqrt{2}}$.

2nd
1st

Next, we act S gate on 1st qubit.

Y_1I_2 and I_1Z_2 stabilize $|0\rangle \otimes \frac{|0\rangle+i|1\rangle}{\sqrt{2}}$.

2nd
1st

	x_1x_2	z_1z_2
Z_1I_2	00	10
I_1Z_2	00	01

	x_1x_2	z_1z_2
X_1I_2	10	00
I_1Z_2	00	01

	x_1x_2	z_1z_2
Y_1I_2	10	10
I_1Z_2	00	01

Applying Clifford gates using binary representation

Applying CNOT gate on c -th control and t -th target qubit

$$x_{it}^{new} = x_{it} \oplus x_{ic}, \text{ for } i = 1, \dots, n$$
$$z_{ic}^{new} = z_{ic} \oplus z_{it}, \text{ for } i = 1, \dots, n$$

We can apply **CNOT** gate by updating the binary table in $O(n)$

Example of Applying CNOT gate

$|0\rangle \otimes \frac{|0\rangle + i|1\rangle}{\sqrt{2}}$ is stabilized by $Y_1 I_2$ and $I_1 Z_2$.
 2nd 1st

Here, we apply CNOT gate on 1st qubit as control and 2nd qubit as target qubit.

$Y_1 X_2$ and $Z_1 Z_2$ stabilize $\frac{|00\rangle + i|11\rangle}{\sqrt{2}}$.

	$x_1 x_2$	$z_1 z_2$
$Y_1 I_2$	10	10
$I_1 Z_2$	00	01

\oplus
 \oplus

	$x_1 x_2$	$z_1 z_2$
$Y_1 X_2$	11	10
$Z_1 Z_2$	00	11
